LEAKAGE CLAMP METER FOR ARRESTER

THE MOST PRECISE LEAKAGE CURRENT CLAMP TESTER IN THE WORLD

Generally, it is said that the metal oxide surge arresters in high voltage lines should be replaced within 15 years after the start of use under the normal conditions:

Of course, the duration of arresters would be shortened by various causes like as direct surge attack, internal abnormal voltage, vibration & shock to outer pole component, etc. and the regular & adequate inspections are required in order to avoid serious accidents in high voltage distribution networks.

In European standard IEC60099-5 Section 6 "Diagnostic indicators of metal-oxide surge arresters", the following inspection methods are introduced:

- *Fault Indicators *Disconnectors *Surge Counters *Monitoring Spark Gaps *Temperature Measurements
- *Insulation Resistance Measurements *Leakage Current Measurements (Capacitive, Resistive, Harmonics, etc.)

Among various methods, the leakage current measurements (except for resistive) are only effective, as others are mostly unreliable under the very severe field conditions and some are impracticable due to impossibility of power line off for inspections.

ALCL-40/ALCL-40L are adapted to "B1" method of IEC60099-5 Section 6.

ACTUAL MEASURING FIELDS

Transformer Substation

Power Line

Railway Station

The most important factor for measuring leakage current is how to detect the real & accurate values (less than 1mA) free from influences of strong magnetic & electric fields in the actual measuring places as above.

Models ALCL-40/ALCL-40L have quite unique & sophisticated CT which enables to measure very low range current with minimum resolution of 0.1μA, depending such outer electric noises.

For example, the comparison list for ordinary & ALCL CT is as followings:

Range	ALCL-40/-40L	Ordinary Model
Accuracy	1.2%	±5%±10%
Minimum Resolution	0.1μA	10μA
Influence of Outer Magnetic Fields	Less than 10μA (400A turn/15cm)	Less than 1mA (20A turn/5cm)

CT CORE STRUCTURE Ordinary ALCL-40

Ordinary

Plane clamp head is easily to become dirty. Magnetic can not coherent with single isolation layer easily.

ALCL-40

Clamp head coherent mutually. Magnetic line is easily to be Conducted. Double-deck insulation & insulation will not be interfered easily.

The operation of such field measuring instruments must be rather simple and easier so that the inspection & maintenance can be made more frequently and the measured data compared correctly, which will lead to find out the problems of surge arresters adequately.

CLAMP EARTH TESTER

MEASURING METHOD of MET-1/MET-2 Clamp Earth Tester

In the equivalent circuit, approx. 160mV p-p (MET-1) or approx.. 320mV p-p (MET-2) is injected from Injection CT by changing frequency from 4 KHz to 400 KHz (MET-1) or 4KHz to 200KHz (MET-2). Then, the resonance will happen by L & C0 or r & C1 in the circuit and the resonance current will flow. At the time of resonance, the current will be maximum. By detecting this resonance current, the current value at resonance point (IZ) and synchronous current at injected frequency can be calculated and the earth resistance can be displayed.

At the time of resonance by L & C0, current I will flow as the above route and can measure Re (Earth Resistance).

*Cannot measure the resistance in no-looping circuit like as grounding line connected with lightning rod but can get the value by connecting with other grounding lines, using the subsidiary lead wire.

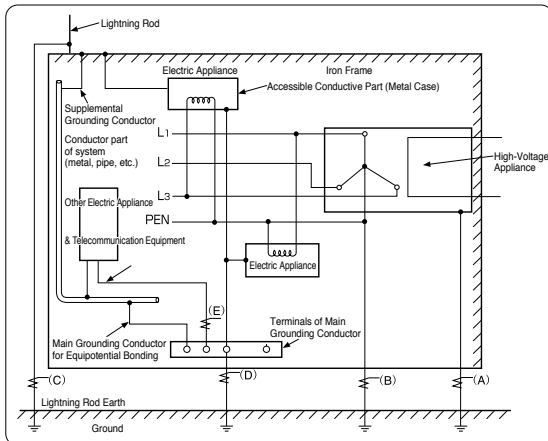

Application Example

① Measurements for the active line

The earth resistance can be measured by clamping 2 CTs near at transformer (point A or B) and near at the electrical loading part (motor, electric appliance, etc.)

② Electric installation

" " shows the clamping point of the injection CT and the measuring CT.

③ Earth resistance measurements for telecommunication system

④ Measurements where L (inductance) & C (capacitance) are low

Where L & C resonance has not been gotten, this instrument may show "OVER" at the display. In this case, connect the objective grounding line (EA) to other grounding lines (EB or ED) by the subsidiary lead wire and clamp 2 CTs at the measuring point (EA). Even in the case of no resonance between L & C, the multiple earth resistance can be measured.

AC/DC CURRENT

FOR AC/DC CURRENT

GROUND FAULT DC CURRENT MEASUREMENT IN PV SYSTEM By Model 730

1. About DC Ground Fault Current in PV System

When the ground fault occurs at the DC current side of power conditioner, DC ground fault current will circulate from the earth to the DC current side of power conditioner via grounding line of boosting transformer & AC current side of power conditioner and then, through the inverter switching circuit. Consequently, DC ground fault current will be superposed to AC current and the current disparity will occur at P&N phase by the content of ground fault current.

2. About Detection of DC Ground Fault Current in Power Conditioner

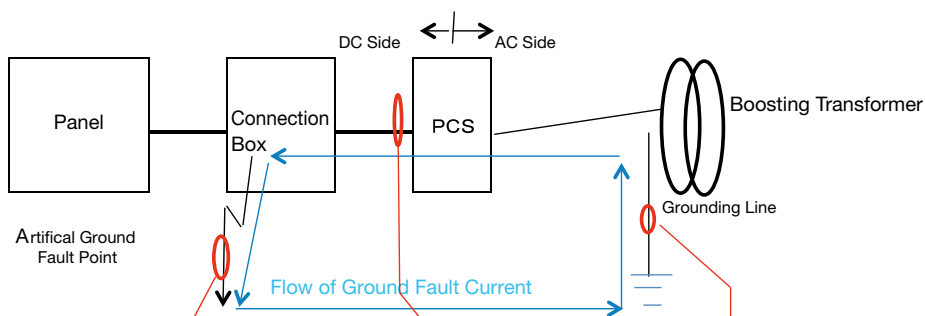

ZCT built in DC current side of the internal power conditioner is monitoring current difference between P&N phase and power conditioner will stop, when the difference exceeds the limited value.

Those limited values are different according to the power conditioner manufactures but they are generally 30mA~100mA.

3. About Measurement of DC Ground Fault Current by DC Current Clamp Tester

After making artificial ground fault (approx. 12mA), measurements of DC current at three places (grounding line of boosting transformer, DC current side of power conditioner and artificial ground fault point) were implemented by DC clamp tester (M-730).

Consequently, the measured values of these three places were almost same, which means that all the DC ground fault current flowed out to AC current end and the current difference of P&N phase at DC current side of power conditioner was almost same as DC ground fault current.

FEATURES

Model 800P is the world's first clamp meter which can detect small DC current in AC circuit in addition to general AC/DC current measurement.

By using this clamp meter, DC offset surveillance can be made easily in the actual fields like as solar inverters, etc. and it is possible to check if the DC component in AC circuit is less than 1% of the rated AC current or not, according to the regulation.

If DC component flows into transformers

In case, the bias magnetism phenomenon may happen and it may cause DC magnetic flux in the iron core. Consequently, it may possibly have bad influence on the connected apparatus by flowing larger excitation current and there would be possibility of transformer burnout due to the selective heating.

Io/Ior DIGITAL CLAMP TESTER

Ior (RESISTIVE) LEKAGE CURRENT MEASUREMENT

BACKGROUND

Nowadays, many harmonics and high-frequency current are contained to leakage current of grounding line and or other circuits due to spread of high-frequency electric apparatus with inverter, converter, etc. and the measured values by different instruments are not same even at the same measuring point.

Generally, leakage current contains the resistive component (I_{or}) which flows to the ground by insulation deterioration and also, the capacitive component (I_{oc}) which flows by electrostatic capacity caused from above high-frequency and harmonics.

The actual insulation deterioration should be related with only I_{or} but ordinary leakage clamp testers can measure only I_o (vector between I_{or} & I_{oc} as under drawings) and cannot judge what kind of leakage current is flowing

containing harmonics (Example)

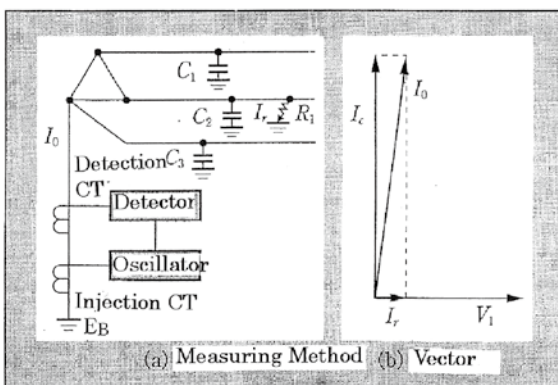

Drawing No.2
Vector of Leakage Current Components

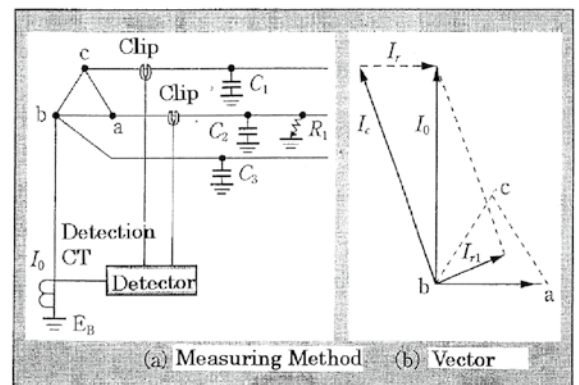

MEASURING METHODS FOR RESISTIVE LEKAGE CURRENT

There are mainly two methods for measuring resistive component of leakage current as followings:

1. I_{gr} Method - Inputting a certain fixed low range frequency to the circuit by injection CT.
2. I_{or} Method – Measuring synchronous current based on the circuit voltage inputted to clamp tester.

Drawing No. 3 I_{gr} Method

Drawing No. 4 I_{or} Method

We are adopting I_{or} method to all our I_o/I_{or} Digital Clamp Testers (except for model MCL-400IR), as I_{gr} method is very difficult to have injection CT in the actual measuring fields.

Our new models MCL-500IRV, 340IRV & MCL-800IRV have non-contact voltage sensors which enable more safely measurement without touching voltage terminals.

Also, model MCL-400IR has very unique method, detecting harmonics (5th & 7th) and measuring resistive component by calculations without voltage input.

FEATURES

Integrated Non-contact Voltage Input Type Clamp Leaker.

*Safety: Available voltage input from the coated conductors (not touching voltage terminal)

*Convenience: Built-in LCD display combined with clamp CT.

It is getting more & more difficult to check the insulation conditions by ordinary Io leakage current due to spread of inverter appliances, etc.

By detecting resistive leakage current (Ior), management of insulation conditions can be made more accurately on the live lines.

FIELD MEASURING INSTRUMENTS FOR PV SYSTEMS

DIFFERENCE FROM ORDINARY INSULATION RESISTANCE TESTERS

Generally, PV systems are generating powers always during day time and the measurement of insulation resistance should be done under live line conditions.

In case of ordinary resistance testers, the generated voltage will have an influence on measured values and in addition, there is a possibility that the tester might be damaged caused by superimposed voltage.

In order to solve this problem, there is a measuring method by short-circuit of P & N phase but it is necessary to prepare the short-circuit breaker, etc. and there is possible danger that electric arcs happen by mis-operation.

MIS-PV series have been developed by taking the above matters into consideration and can measure insulation resistance accurately & safely even during PV generation without short-circuit by its unique designs.

By using MIS-PV series, safer and more efficient works for insulation resistance measurement of PV generating panels can be realized.

Model MIS-PVS TECHNICAL GUIDE

GENERAL

We developed the insulation resistance tester which can measure insulation resistance at solar panels easily under generating condition. (Patent Pending).

The ordinary insulation resistance testers cannot measure resistance correctly during generation but model MIS-PVS can make measurement easily regardless of generating or no power and also can display the insulation failure point. (at P phase side, N phase side or between modules).

- (1) Indicate the insulation failure point of PV systems
- (2) Can measure the insulation resistance at solar panel side under generating conditions by one operation.
- (3) Can measure the insulation resistance of ordinary electrical equipment.

MEASUREMENT

- ① Make the disconnecter off.
- ② Apply N clip of the tester to N phase side.
- ③ Connect E clip to grounding earth side.
- ④ Apply the probe to P phase side of solar panel.
- ⑤ Set the measuring switch of MIS-PVS on.
- ⑥ The insulation resistance value is displayed on LCD.
- ⑦ In case of the measured value less than $1M\Omega$, P1~P12 on LCD display will be lightening. When P3 is lightening, there is an insulation failure at the place between 3/10 and 4/10 of whole modules. P1 will be lightening in case of the insulation failure at P phase side and P11 will be lightening in case of failure at N phase side.

Drawing 1. How to display the insulation failure point

Model MIS-PVS TECHNICAL GUIDE

THEORY of Indication for insulation failure point

As shown on the drawing 2, considering that an insulation failure (R_x) happens between solar panel modules and provided that the generated voltage of PV system is V_0 and the voltage from insulation failure point to P phase terminal is V_x . Also, provided that applied voltage is V_1 and current is I_1 .

Drawing 2. Circuit Diagram in case of applying voltage to solar cell

When measuring the insulation resistance two times by changing voltage, provided that the first applied voltage is V_1 , current I_1 and the second applied voltage is V_2 , current I_2 , the drawing 3 is showing the relation between these applied voltages and currents.

The intersection point V_x with horizontal axis (current $I=0$) on the drawing 3 is showing the generated voltage of solar panel from P phase to the insulation failure point. The insulation failure point can be specified by the ratio of the generated voltage of solar panel V_0 to the generated voltage to failure point V_x .

Drawing 3. Relation between applied voltage, current value and insulation failure point
